

- 28 Chymotrypsin is an enzyme that hydrolyses proteins into smaller peptides and amino acids. It specifically hydrolyses the peptide bond on the carboxyl side of a residue that contains an aromatic ring. For example, the pentapeptide W produces **only** the three compounds X, Y and Z. X and Y are dipeptides.

Which of the four tetrapeptides on page 15 will form two different **dipeptides** when hydrolysed by chymotrypsin?

**A****B****C****D**
